TELEHEALTH AND PREDIABETES

ABSTRACT

Chronic conditions are a considerable burden on the healthcare system, and one that is becoming increasingly prevalent is diabetes. Prediabetes is a condition that has become more common and diagnosed in many patients before an actual diagnosis of diabetes. Healthcare professionals strive to empower individuals to make lifestyle changes to prevent diabetes from occurring by informing individuals on how to manage prediabetes. For individuals that do not make the necessary changes to lower their hemoglobin A1c to below the standards of less than 5.6%, a diagnosis of diabetes occurs. It is estimated that five per 1000 individuals are diagnosed with prediabetes; however, research reveals that many people do not even know they have prediabetes. The number of individuals with prediabetes is consistently on the rise, ultimately increasing the number of individuals with Type 2 diabetes. Providing individuals with the necessary tools for improved lifestyle modifications will decrease the likelihood of developing Type 2 diabetes. This integrative review evaluates evidence-based, peer-reviewed, published articles on the effectiveness of increasing awareness of the necessary lifestyle behaviors for the prevention of diabetes through telehealth education. The literature supports that telehealth can improve lifestyle behaviors, including improved eating habits and increased physical activity, thus reducing hemoglobin A1c levels, body weight, or body mass index of individuals with prediabetes.

TELEHEALTH AND PREDIABETES

Acknowledgments

First, I want to acknowledge God for the guidance and wisdom provided throughout this journey. If it weren't for the Holy Spirit reminding me of the vision placed within my heart and pushing me to continue during times of being in the valley, I wouldn't be where I am at today. I want to thank my amazing husband, who supported me through this endeavor, my two sons, and my beautiful granddaughter, who also provided love and support during this journey. I will be forever dedicated to you for all you have done for me. I also want to thank my friends and mentors, who guided and reassured me I could complete this journey. Finally, I would like to thank all the faculty at Liberty University for their guidance and support. I am grateful for the academic experience I received at Liberty University.

TELEHEALTH AND PREDIABETES

SECTION ONE: FORMULATING THE REVIEW QUESTION

Introduction

Diabetes is a chronic condition that affects millions of individuals worldwide, and the number of patients diagnosed is rising. This unfortunate growth requires the healthcare systems to increase awareness within the community. As the nation continues to battle this condition and the complications that can arise, it is crucial to implement educational strategies for individuals in the prediabetes stage. Prediabetes is a precursor to Type 2 diabetes (T2DM). Recent data estimates that over 33% of adults over 18 years of age have prediabetes, and 70% will be diagnosed with T2DM (Batten et al., 2022). Somerville et al. (2019) conducted research revealing that T2DM could be decreased by 58% with positive lifestyle modifications, which coincides with the national statistics of the Centers for Disease Control and Prevention (CDC). The increased healthcare costs for individuals with T2DM are roughly over \$16,000 annually, which is approximately two times the medical expenses of a person without diabetes (www.cdc.gov/diabetes). On a global concern, current data estimates that in 2016, 422 million individuals had diabetes; in 2019, a rise to 463 million people, and by the year 2045, it is estimated that over 700 million people will be affected by diabetes (www.cdc.gov/diabetes, AshaRani et al., 2021). The financial burden associated with diabetes care is estimated to be \$850 billion globally (Olson et al., 2022). Unfortunately, diabetes is considered the seventh leading cause of death in the United States (www.cdc.gov).

The goal is to encourage and empower individuals with prediabetes to make the necessary lifestyle modifications to prevent T2DM (Somerville et al., 2019). However, the fast-paced lifestyle of people places them at higher risk of prediabetes due to not understanding the seriousness of the condition. Unfortunately, the nation is seeing an increase in food insecurity,

TELEHEALTH AND PREDIABETES

and unhealthy eating habits are prevalent; fast-food access is becoming increasingly available, and individuals are increasingly becoming more sedentary, all the factors leading to prediabetes (Bakre et al., 2022). As adults continue to practice these unhealthy behaviors, they increase their risk for prediabetes. Healthcare professionals will see an increase in clinic visits and hospitalizations due to the rise in chronic conditions, thus burdening the healthcare system (Jeihooni et al., 2019). As more individuals face challenges with diabetes management leading to higher levels of blood glucose, the incidences of other comorbidities rise. Individuals with diabetes tend to have complications consisting of neuropathy, cardiovascular disease, and renal disease (Olson et al., 2022).

The data supports that positive lifestyle modifications can prevent the onset of T2DM by empowering individuals to make the necessary changes (Cannon et al.; 2022, Falguera et al.; 2020; Gosak et al., 2022). The outcomes of positive lifestyle modifications consist of a lower body mass index (BMI), decreased body weight, improved glycemic control, increased exercise, and improved dietary habits. As poor management of diabetes continues to rise, it is crucial to gain insight into how a telehealth educational program provides the necessary evidence-based tools for individuals to make the required lifestyle modifications for those with prediabetes. Telehealth research has indicated increased appointments due to ease of access and cost-effectiveness and provides the necessary resources for the underserved (Shakya et al., 2021).

National Diabetes Prevention Program and Diabetes Self-Management Education and Support

Addressing the appropriate lifestyle behaviors allows individuals to achieve improved hemoglobin A1c (HbA1c), the standard in measuring an individual's average glucose levels within three months (www.diabetes.org). The National Diabetes Prevention Program (NDPP)

TELEHEALTH AND PREDIABETES

and Diabetes Self-Management Education and Support (DSMES) are programs geared to increase the knowledge base of individuals (www.cdc.gov, Litchman et al., 2022). The NDPP provides the foundational framework for healthcare professionals to use to help prevent T2DM from occurring. In comparison, DSMES supports the foundation and resources for the daily management of diabetes.

Olson et al. (2022) established the framework for effective diabetes education to ensure the platform provides quality and consistency as it provides the nation with the tools to manage this chronic condition. Two outcomes are associated with positive behavior changes and education; improved clinical outcomes and reduced costs. Four indicators related to diabetes education include improved knowledge, understanding of the condition, self-management, and self-determination. A framework established and utilized nationwide in all educational services will help to achieve the desired outcome of reducing the number of individuals with T2DM.

A crucial component of addressing lifestyle behaviors in preventing diabetes is the role of telehealth as an educational platform. Our fast-paced society places a greater emphasis on technology. Telehealth has provided the healthcare system more opportunities to meet individual needs (Aberer et al., 202, Cannon et al., 2022). Telehealth has also been shown to be cost-effective, more practical for individuals, and offers broader access to the underserved. Given the tools it provides individuals with, the outcome of telehealth has proven to lower HbA1c and empower individuals to make the necessary lifestyle behaviors (Aberer et al., 202, Gosak et al., 2022). Kasturiratne et al. (2021) conducted a study supporting the importance of lifestyle modifications to help prevent the onset of T2DM, which can be achieved using technology. The study found that the platform's benefits included reducing patient visits, allowing broader access, and being cost-effective for healthcare professionals and individuals.

TELEHEALTH AND PREDIABETES

Telehealth Education

It is crucial to distinguish between telehealth and telemedicine within the parameters of the literature review. Telemedicine consists of a one-on-one online visit with a healthcare professional. Conversely, telehealth comprises any technology utilized to improve health (Aberer et al., 2021, Roy et al., 2022). Examples of telehealth within prediabetes and T2DM consist of mobile applications, Mhealth, continuous glucose monitor (CGM), telephone, dietary and exercise tracking programs, mobile applications, and group educational programs using technology; telediabetology is specific to diabetes management (Aberer et al., 2021 Stotz et al., 2020). A crucial component of the utilization of telehealth is the broader range of materials and independence for the individual and provider. However, it also provides the ability to reach those with limited transportation (Olson et al., 2022). Current data also indicates that individuals are more likely to keep telehealth appointments than clinic appointments (Alaslwi et al., 2022).

A necessary component of using telehealth is understanding the individuals utilizing the technology. Since Covid 19, the use of technology has tripled in providing patient care; thus, improvements are continuous. Signal et al. (2020) offer valuable insight into using technology as an intervention by addressing factors associated with technology and individuals. The related aspects must be assessed using technology: “age, motivation, personal values, digital literacy, and family support” (Signal et al. 2020, p. 2), which are essential aspects to note for the development of a program.

Defining Concepts and Variables

The purpose of this integrative review (IR) was to understand how telehealth can improve an individual's lifestyle behaviors, reducing weight and increasing PA, thus decreasing their HbA1c and reducing the risks of diagnosis of diabetes. The Toronto and Remington criteria

TELEHEALTH AND PREDIABETES

(2020) ensured a comprehensive review by including the process's crucial steps. T1DM is an autoimmune condition where the pancreatic beta cells no longer produce insulin, the hormone required to decrease blood glucose levels. The insulin mechanism of action attaches to the glucose molecule and transports it into the cell for energy. These individuals need lifelong insulin injections in addition to lifestyle behaviors; this condition accounts for less than 10% of the population (www.diabetes.org). Gestational diabetes occurs during pregnancy when the pancreas cannot sustain adequate amounts of insulin. T2DM is a condition that has some genetic factors but is mainly related to lifestyle. T2DM is diagnosed with a fasting blood glucose of 126 or greater and an HbA1c greater than 6.4%. Glycosylated hemoglobin A1c (HbA1c) measures the glucose amount attached to a red blood cell within three months (Sevilla-Gonzalez et al., 2022).

The standard recommended by the American Diabetes Association (ADA) for individuals without diabetes is less than 5.7% (www.diabetes.org). The concern with the increased glucose levels in the blood (hyperglycemia) can cause damage to vessels. This damage can be microvascular and macrovascular, which is irreversible. Education on diabetes can empower individuals to make the necessary lifestyle changes to limit the damage that occurs. (Olson et al., 2022). The American Diabetes Association (ADA) defines prediabetes as having an HbA1c of 5.7% to 6.4%. A diabetes diagnosis occurs with an HbA1c of 6.5% or greater. To reduce the risk of micro and macrovascular complications, the CDC and ADA recommend individuals with diabetes achieve an HbA1c of less than 7%; to achieve these levels, the time-in-range (TIR) of blood glucose range must be more than 70% (www.diabetes.org).

Additional defining variables consist of monitoring blood glucose levels to maintain target levels. Glucose meters allow individuals to monitor their glucose levels daily. This device

TELEHEALTH AND PREDIABETES

requires individuals to complete a finger stick to apply a drop of blood to a strip inserted into the meter. The meter analyzes the blood to determine the reading. The individual then decides the course of action to maintain the blood glucose level that will return blood glucose to the target. However, as technology has advanced in healthcare, there are numerous options for individuals with diabetes for monitoring. Continuous glucose monitoring (CGMs) has provided individuals with diabetes with the necessary tools for easier access to monitoring (Farhan et al., 2022). In addition, the technology behind CGMs offers more accessible access to treatment plan changes via methods other than face-to-face visits (Aberer et al., 2021).

Individuals must engage and understand the interventions to achieve healthier lifestyle modifications to maintain their target blood glucose level (Falguera et al., 2020, Stotz et al., 2020). Nutrition, especially carbohydrates, is critical to maintaining adequate blood glucose levels between 70-110, or target levels provided by healthcare professionals (Bakre et al., 2022). In addition, another defining variable is exercise or physical activity (PA). It is essential to understand how cells and insulin respond to movement. With exercise or physical activity (PA), cells become more sensitive to letting insulin in, thus lowering blood sugar naturally. Individuals with diabetes should achieve 150 minutes of moderate weekly activity (Batten et al., 2022). Physical activity (PA) has added benefits concerning health status; it decreases stress levels, improves sleep, decreases weight, and improves heart health (www.cdc.gov; Batten et al., 2022; Dagogo-Jack et al., 2022).

Rationale for Conducting the Review

As prediabetes continues to rise, individuals must adapt their lifestyles to prevent the diagnosis of T2DM from occurring. Individuals seek more medical care due to uncontrolled diabetes or complications arising from diabetes, which involves implementing an intensive

TELEHEALTH AND PREDIABETES

telehealth program that improves access to care (Olson et al., 2022). The program aims to improve HbA1c, maintain lower glycemic measures, and promote lifestyle behaviors crucial in managing diabetes. Current research has revealed that the complications of diabetes pose a serious concern to individuals' morbidity and mortality. The goal of preventing T2DM is to empower individuals, when informed they have prediabetes, to make the necessary lifestyle behavior modifications (Cannon et al., 2022).

Purpose of Review Question

The burden of diabetes complications around the globe is a vast concern, and gaining an insight into what is required to help individuals achieve a healthier lifestyle for the prevention of diabetes is crucial. Aiming to decrease individuals' prediabetes HbA1c levels to under 5.7% is necessary to prevent T2DM from occurring. Instilling adequate lifestyle modifications and behaviors through successful telehealth education to achieve optimal patient outcomes is essential. Individuals require more accessible access to information that telehealth provides. Recent studies have detailed that lifestyle modifications are necessary for preventing and managing T2DM. The results of individuals participating in a telehealth educational series on improving lifestyle behaviors have resulted in a lower HbA1c, reduced weight, and increased weekly exercise or PA, thus lowering the risk of developing T2DM (Dagogo-Jack et al., 2022).

Clinical IR Question

Does the literature support the use of telehealth education to improve the lifestyle behaviors of adults with prediabetes?

TELEHEALTH AND PREDIABETES

Inclusion and Exclusion Criteria of the Literature

A crucial component of the IR is defining the clinical question to be addressed to guide comprehensive literature research. Once the question was developed, formulation of the inclusion and exclusion criteria must be identified (Toronto & Remington, 2020). Inclusion criteria comprised peer-reviewed, evidenced-based articles reviewing the relationship between telehealth and lifestyle modifications for prediabetes and T2DM and the effects on lowering HbA1c. However, additional inclusion criteria included the English language between 2018-2022. The exclusion criteria included T1DM, T2DM individuals on insulin, and gestational diabetes. In addition, exclusion criteria consisted of any pediatric population with diabetes.

Consultation with diabetes care and education specialist (CDCES) within the local community provided vast knowledge on the topic. Moreover, the librarian's assistance locating substantial journal articles was crucial in implementing the IR. Disciplines associated with the search criteria included Certified Diabetes Care and Educational Specialists (CDCES), Diabetes Nurses, Physicians, Registered Dietitians, and Public Health Nurses.

Conceptual Framework

Whittemore and Knafl (2005) provided the framework and analysis method to ensure the IR's purpose was addressed and aligned appropriately. It was also crucial that the literature is accurate and organized within the IR. An extensive literature evaluation concerning various parts of the question was essential. The articles were analyzed in detail to ensure they met the necessary review components to provide in-depth knowledge of the clinical question (Toronto & Remington, 2020). This IR framework included the relationship between lifestyle behaviors and the reduction of HbA1c, weight loss, increased exercise, and the prevention of T2DM.

TELEHEALTH AND PREDIABETES

Theoretical Framework

The theoretical framework highly recommended for individuals with prediabetes to be used by healthcare professionals is the RE-AIM model (www.re-aim.org). This model provided a foundation for health promotion and has been used in corporations to implement new knowledge (Tschida et al., 2021). Knowledge and understanding of lifestyle modifications are essential for individuals with prediabetes. The model distinguishes how effective the interventions are for change. A factor to consider was that individuals must participate in the interventions provided by the telehealth program to achieve the desired outcome. The utilization of the model provides the resources for behavior changes (Olson et al., 2022). The interventions aim to achieve a lower HbA1C by incorporating lifestyle modifications, healthier eating habits, and increased physical activity, reducing body weight or BMI (Signal et al., 2020). Research has shown that with lifestyle modifications, there is a 58% decrease in type 2 diabetes occurring (www.cdc.gov, www.healthypeople.gov).

SECTION TWO: COMPREHENSIVE AND SYSTEMATIC SEARCH

In developing the IR, it was essential to review articles to help determine the evolution of the practice or the need to research the phenomenon further. Appendix A delineates studies on diabetes management, lifestyle management, and telehealth implications supporting evidence that a telehealth program is effective (Evans et al., 2021, Lewinski et al., 2022, Litchman et al., 2022). The literature reviewed revealed extensively that diabetes management requires lifestyle changes. Lifestyle behaviors delineated in the research included exercise, monitoring blood glucose, and maintaining a healthy balanced diet. An essential element within the literature review stated that education was crucial to the management and needed early intervention and ongoing support to be effective (Cannon et al., 2022, Celik et al., 2022, Olson et al., 2022). With

TELEHEALTH AND PREDIABETES

the vast improvements in technology and diabetes management, using telehealth to engage individuals provides the necessary tools for behavior modification, including improved eating habits and PA (Evans et al.; 2021, Lewinski et al.; 2022, Litchman et al.; 2022).

Search Organization and Reporting Strategies

The search strategy for this IR was obtained through five databases using a systematic approach (Toronto & Remington, 2020). CINAHL, ProQuest, PubMed, government and local websites, and American Diabetes Association (ADA). The keywords used in the search were diabetes, diabetes and technology, telehealth, telemedicine, lifestyle modifications, diabetes, National Diabetes Prevention Program (NDPP), Diabetes Self-Management Education and Support (DSMES), exercise, and nutrition. The review provided over 100 articles about answering the clinical question related to diabetes and education; however, only 45 were peer-reviewed. Approximately 29 articles were peer-reviewed due to the recently implemented telehealth uptake and NDPP. Twenty-nine articles met the inclusion criteria to be utilized in the IR.

A crucial element within this IR and the literature associated with the clinical question was the analysis of literature using Mylenke-Level Evidence (Melnyk & Fineout-Overholt, 2018). Developing the IR requires detailed research of the studies conducted to understand the clinical question relationship, quality, and validity of the addressed concern.

Terminology

For this IR, the search included the term *database*, the electronic collection of materials from the Jerry Falwell Library at Liberty University (Toronto & Remington, 2020). The

TELEHEALTH AND PREDIABETES

investigation also involved databases that correlated statistics, including government, local, and international sites.

SECTION THREE: MANAGING THE COLLECTED DATA

An essential process of developing the IR was the review and analysis of the literature review. Melnyk and Fineout-Overholt, (2018) outlined the process for the literature matrix; Appendix A delineates the evidence-based peer-reviewed articles used for this IR. Articles were carefully screened based on wording and topic, including Diabetes Prevention, NDPP, DSMES, prediabetes, T2DM, behavioral modifications, telehealth, lifestyle modifications, nutrition, and exercise. In addition, the articles were analyzed to ensure consistency in data to formulate the knowledge for the clinical question to be addressed.

SECTION FOUR: QUALITY APPRAISAL

Sources of Bias

An essential aspect of a literature review was identifying potential sources of bias. Bias within research can inhibit the validity or trustworthiness of the research data (Toronto & Remington, 2020). However, reviewing the literature was completed by a single researcher using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses 2020 (PRISMA) checklist; all criteria were analyzed (Page et al., 2021). Studies must be designed and analyzed that minimize bias. If there is any form of discrimination within a study, it loses its trustworthiness. Articles written in the English language were the only articles reviewed. However, the articles reviewed were global.

Potential sources of bias within this research consisted of demographics and measurements of weight. Providing the nature of this IR was examining lifestyles on the effects

TELEHEALTH AND PREDIABETES

of preventing T2DM from occurring for individuals with prediabetes; it was essential to ensure lifestyle behaviors were outlined within each of the studies analyzed to ensure accuracy.

Internal Validity

It was essential to ensure scientific methods were utilized to analyze studies for internal validity (Toronto & Remington, 2020). External validity can be compromised if internal validity is skewed or not established. To answer the IR clinical question, the research articles needed to demonstrate internal validity (Melnik & Fineout-Overholt, 2018). Upon analysis of the literature, internal validity was established by indicating that lifestyle behaviors, such as exercise and eating habits were indicators that affect individuals with prediabetes.

Appraisal Tools (Literature Matrix)

An essential part of conducting a study to answer the clinical question was to analyze the research appropriately according to the type of literature being reviewed (Toronto & Remington, 2020). Considering there is no best way to appraise a study accurately, the researcher conducting the IR must be aware of and ensure the same appraisal tool is used for all studies analyzed. There are over 100 appraisal tools, nine of which are highly utilized within the healthcare profession. The appraisal tool used for this IR was the Melnyk and Fineout-Overholt Level of Evidence (Melnik & Fineout-Overholt, 2018).

The initial step within the review consisted of gathering data and ensuring the clinical question's relevance. The nature of this IR examined prediabetes or prevention of T2DM, telehealth, and education, and then the research was separated into categories to ensure relevant topics were addressed. The types of evidence ranged from a systematic review or meta-analysis (Level 1) to Expert Opinion (Level VII), outlined in Appendix A (Melnik & Fineout-Overholt,

TELEHEALTH AND PREDIABETES

2018). In addition, Appendix C summarizes the categories of research annotated to answer the clinical question.

The review comprised 29 articles on prediabetes, prevention of T2DM, telehealth and prediabetes or T2DM, and lifestyle modifications. Of the 29 articles reviewed, five were Level I; eight were Level II, four were Level III, three were Level IV, four were Level V, and five were Level VI. Even though Level VI is lower within the Hierarchy of Evidence, they provided valuable insight into the topic. All levels were included in the review to meet the rigors of research (Melnik & Fineout-Overholt, 2018, Toronto & Remington, 2020). The lifestyle modifications achieve a desired lower HbA1c, FBS, FPG, weight, or BMI.

Applicability of Results

Current research supports that education is critical for individuals with prediabetes to prevent T2DM. Educational requirements include addressing lifestyle modifications to incorporate healthy eating habits, increasing or engaging in PA, decreasing stress, and decreasing weight or BMI.

Reporting Guidelines

A crucial step within an IR is the data acquired to answer the clinical question. However, the PRISMA guideline is the preferred method for systematic reviews (Toronto & Remington, 2020). Page et al. (2021) provided detailed procedures for conducting the IR to ensure each article met the requirements. Each article reviewed was evaluated to ensure it was applicable in addressing the clinical question regarding telehealth, education, prediabetes/diabetes prevention, and DSMES. Appendix B, the PRISMA flow diagram, outlines the data collection.

SECTION FIVE: DATA ANALYSIS AND SYNTHESIS

TELEHEALTH AND PREDIABETES

Data Analysis Methods

A crucial step within the IR was to have a vast understanding of the topic's primary purpose and the IR's goal. Within this IR, evaluating the literature to increase knowledge of the categories crucial to answering the clinical question was essential (Toronto & Remington, 2020). This IR aims to provide insight into the benefits of telehealth education to improve the lifestyle behaviors of adults with prediabetes. The literature examined included various elements of lifestyle behaviors, including knowledge of individuals and healthcare professionals on diabetes, nutrition, and exercise. In addition, articles addressed face-to-face or telehealth education to understand its role in individuals with prediabetes or T2DM.

Article Theme Discussion

The literature was categorized into four main themes to address the clinical question: readiness and knowledge, National Diabetes Prevention Program, lifestyle, and telehealth. Each theme represents crucial information for healthcare professionals to understand to empower individuals with prediabetes to make those lifestyle modifications. The following section will discuss each of the article themes in detail.

Readiness and Knowledge

Among the articles reviewed, six emphasized knowledge, readiness, and behavior as crucial elements for success in individuals with prediabetes to make the necessary lifestyle modifications. A common theme noted within four of the studies consisted of individuals who are not ready for behavioral change will not be open to making the necessary lifestyle modifications (Annie Kao et al., 2021; Davis-Ajami et al., 2021; MohammadniaMotlagh et al., 2022; Teoh et al. 2023). In addition, Teoh et al. 2023, Davis-Ajami et al. 2021, and Speaker et al.

TELEHEALTH AND PREDIABETES

2021 studies recognized the importance of healthcare professionals' knowledge of prediabetes and informing patients to make those essential lifestyle recommendations. In addition, Somerville et al. and Speaker et al. research reported that healthcare professionals recognize lifestyle modifications of physical activity and improved nutritional habits could reduce the progression to T2DM by 58%. Nutrition, a cornerstone of prediabetes management, is not being referred by HCPs for individuals to increase their knowledge of nutrition (Somerville et al., 2019; Speaker et al., 2021). Eleven percent (1881) of individuals within Speaker et al.'s study received Medical Nutrition Therapy (MNT) referrals, and Somerville et al.'s study had 21% of individuals receive a referral. However, Speaker et al. (2021) reported only 7.4% (140) had at least one visit, and 1% of people with prediabetes saw a nutritionist. However, the studies identified that for lifestyle modifications to occur, they must begin with an internal behavior change (Annie Kao et al., 2021; Davis-Ajami et al., 2021; MohammadniaMotlagh et al., 2022; Teoh et al., 2023). One key element noted within the research completed by MohammadniaMotlagh et al. was that education based upon theory shows positive effects; however, there was a significant increase in physical activity compared to an improvement within the intervention group. Given minimal diet improvements, fasting blood sugar (FBS) improved from 106 to 99.70 after education. In addition, the research revealed that after education or advice for lifestyle modifications was adhered to, individuals who increased or started an exercise program reduced their BMI. The results provided evidence that self-management, self-efficacy, and knowledge are critical components to reducing the prevalence of T2DM.

TELEHEALTH AND PREDIABETES

National Diabetes Prevention Program

The development of NDPP is a CDC-recognized program established to prevent T2DM (<https://www.cdc.gov/diabetes/prevention>). The Azzi et al. (2020), Cannon et al. (2022), and Kirley & Sachdev (2018) studies recognized the relevance of the program for individuals with prediabetes. Azzi et al.'s finding aligned with Cannon et al., indicating that these programs motivate behavior change by providing the necessary tools. However, Kirley & Sachdev's study reduced the risk of T2DM by 27% with the lifestyle change program (LCP), including a weight reduction of 4.7%, and Azzi et al.'s study showed an 85% increase in knowledge in nutrition and a 74% increase in physical activity through the NDPP.

Lifestyle Interventions

Six articles reviewed focused on lifestyle interventions to prevent T2DM (Azzi et al., 2020, Celik et al.; 2022, Dagogo-Jack et al., 2022; Ghisi et al., 2021, Mash et al., 2022, Salmon et al.; 2021). Dagogo-Jack et al. findings revealed that with lifestyle modification, people with prediabetes could reduce their risk of T2DM between 30-60%, comparable to the CDC standard of 58% reduced risk of T2DM with lifestyle interventions implemented early upon diagnosis of prediabetes (<https://www.cdc.gov/diabetes/prevention>). Mash et al. showed an increase in physical activity by 53% and nutrition knowledge and positive diet changes by 76%.

The Celik et al. (2022), Idris et al. (2022), Litchman et al. (2022), Mash et al. (2022), and Leong et al. (2022) studies recommend Diabetes Self-Management Education and Support (DSMES) for lifestyle behaviors in order to manage diabetes. Diabetes is a chronic condition that requires healthy eating and exercise to maintain target blood glucose. Ghisi et al. study viewed the phases to establish an educational program, and the study reported that DSMES is a powerful tool for behavior change in individuals with prediabetes. The guidelines established for T2DM

TELEHEALTH AND PREDIABETES

management can apply to prediabetes, given that prediabetes is the precursor to T2DM. Celik et al. (2022) study showed that 78.5% of patients received instruction from the educator within the year, whereas 46.7% received one time, 27.7% received education twice, and 25% of individuals received education more than three times; Leong et al. (2022) study evaluated education through the social media platform. Those individuals who received instruction three or more times had decreased their HbA1c by 1% (Celik et al. 2022) and increased their diabetes knowledge from 68.3% to 76% (Leong et al. 2022).

Yin et al. (2022), Salmon et al. (2022), Sevilla-Gonzalez et al. (2022), and Zimmermann et al. (2022) studies reported similar results in changes in HbA1c, BMI, FBG, or FPG. Yin et al.'s study revealed HbA1c percentage of 8.56 at baseline decreased by a mean of 1.63 percent after a 6-month follow-up lifestyle telehealth intervention, and Sevilla-Gonzalez et al.'s study showed a significant change in HbA1c from 5.9 to 5.8, after the 3-month intervention.

Yin et al.'s study had effective WL; BMI averaged 29.25 at baseline to 25.49 after the 6-month intervention follow-up. Zimmerman et al.'s study had approximately 12% WL between the four quarters. However, after the 5-year follow-up, WL maintained a 3.7% drop. In contrast, Sevilla-Gonzalez et al.'s study revealed a WL of 3.4 Kg and a waist circumference (WC) decrease of 3.9 inches after the intervention.

Yin et al.'s (2022) and Salmon et al.'s (2022) studies revealed a change in FBG with intervention. Yin et al.'s baseline average FBG of 8.45 mmol/L after a 6-month telehealth lifestyle intervention; FBG decreased to 5.58 mmol/L; Salmon et al. study viewed FBG categorized upon BMI; mean 5.8-5.9 mmol/L between BMI 18.5 - >30 Kg reduced by 0.4 within BMI 18.5-24.9 kg group, 0.3 decreases within BMI 25.0-29.0 kg group, and a decrease of 0.3 kg

TELEHEALTH AND PREDIABETES

within the BMI >30 kg group. Sevilla-Gonzalez et al. (2022) and Zimmerman et al. (2022) studies showed a reduction in FPG, averaging a three-point drop (Sevilla-Gonzalez et al. 2022); 5.8 in quarter one to 5.6 in quarter four (Zimmerman et al. 2022).

Telehealth

Articles focused on telehealth as a platform were critical to answering the IR clinical question. Alaslawi et al. (2022), Idris et al. (2022), and Lewinski et al. (2022) provided the foundational instrument for understanding telehealth and what future research needs to occur, as well as the role telehealth plays in empowering individuals. The systematic review completed by Lewinski et al. examined over 8,000 articles on telehealth and chronic disease, 80% of which focused on T2DM. One of the studies showed a decrease in HbA1C from 9.5 to 8.6. However, Alaslawi et al. and Idris et al. revealed that the younger population is more consistent with interactive technology. Technology provides the opportunity to increase communication with providers. Given that the prevalence of prediabetes is more prevalent in younger individuals, mobile applications are suitable means of education for this generation.

Ahn et al. (2023) studied dietary coaching in addition to the use of CGM and compared it to a control group that received formal education on diet and exercise. CGM is a telehealth platform that is effective in reducing HbA1c and improving dietary habits. The studies completed by Annie Kao et al. (2021) and Zimmermann et al. (2022) utilized telephone and weekly feedback as the telehealth platform intervention. Both of these studies revealed that self-efficacy was crucial for behavior modifications. Weight loss (WL) occurred in the six-week nurse-led intervention (Annie Kao et al. 2021), but no significant change occurred in HbA1c; understandable six-week is a short duration to see a difference in HbA1c. Over the five-year study (Zimmermann et al., 2022), there was substantial WL within the first two months. This is

TELEHEALTH AND PREDIABETES

crucial information regarding weight as a factor for prediabetes, as noted within the following studies Annie Kao et al., 2021; Salmon et al., 2021; Zimmermann et al., 2022. WL within the Annie Kao et al. (2021) study was accompanied by a decrease in blood pressure, indicating cardiac health improvement. Salmon et al., 2021 provided counseling on nutrition and exercise through a telehealth platform to decrease individuals' FPG; thus, 45% of individuals returned to normalized FBG over six months and increased physical activity from 65 minutes to 122 minutes for individuals with BMI >30.

The Alaslawi et al. (2022), Alshehri and Alshaikh (2021), Batten et al. (2022), Cannon et al. (2022), Kasturiratne et al. (2021), Kirley & Sachdev (2018), Salmon et al. (2021), Sevilla-Gonzalez et al., (2022), and Signal et al., (2020) studies concluded that the use of mobile applications and delivery of education via a telehealth platform was a successful tool for self-management of individuals with prediabetes. Specifically, Batten et al., Cannon et al., and Kirley and Sachdev's studies focused on NDPP implemented digitally. Cannon et al. study viewed NDPP programs through various methods, including face-to-face, digital, distance, and hybrid, from 2012 to 2019, with 455,954 individuals enrolled. The breakdown consists of approximately 166,000 in-person, 260,000 online, 4756 for distance learning, and over 15,000 for hybrid or a combination. Highlights of the demographics include in-person had the lowest number of men enrolled, 19.4%. In comparison, men had a higher enrollment number in the online platform, approximately 27.1%. Other demographics were reasonably distributed across each ethnicity. The in-person average age was about 65 years, whereas the online enrollment had 41.5% of 18-44 years old registered. Statistically speaking, the number of telehealth-registered individuals provides a framework that telehealth is suitable for delivering education.

TELEHEALTH AND PREDIABETES

Alshehri and Alshaikh (2021) conducted a cross-sectional study using self-administered questionnaires administered in phases to gather data on the telehealth program's introduction, adoption, and employment phases. The goal was to collect data from healthcare professionals, including physicians, dieticians, and health educators, on telehealth applications in diabetes prevention. The findings revealed that healthcare professionals believed mHealth is beneficial for individuals with prediabetes to improve their lifestyles. Besides healthcare professionals, the study also examined patients' perceptions of telehealth. Over 75% of individuals with prediabetes were open to telehealth; the other 25% stated they may be open to it. Studies that examined the implementation of lifestyle behavior modification for preventing diabetes through telehealth research were completed by Alshehri and Alshaikh (2021) and Signal et al. (2020). Specifically, these studies analyzed the elements of implementing a telehealth education program. Signal et al.'s (2020) study included 429 individuals in a telehealth program called the betaMe/Melon program, which included a Random Control Trial, with 214 participants in the control group and 215 in the intervention group. Signal et al.'s (2020) findings revealed improved knowledge that leads to better management, which decreased HbA1c and WL through the health coaching app. Alshehri and Alshaikh's (2021) findings showed a decrease of 5% in body weight with a mobile application. Moyaka et al. (2022) analyzed 12 articles that revealed the intervention group had an HbA1c change between 0.10 to 2.83 decrease and FBG from 173 to 131 compared to the control group.

A crucial step for determining a telehealth program's effectiveness is evaluation. Both Batten et al. and Sevilla-Gonzalez et al.'s research provide insight into the assessment of delivering a web-based platform educational program. Sevilla-Gonzalez et al. examined the effects after a three-month intervention; results showed improvement in FBG, body fat

TELEHEALTH AND PREDIABETES

percentage, and waist circumference (WC). A concern noted within the study was the user interface with technology, and the researchers recommended that individuals have a solid understanding of the technology used before implementation. Batten et al. evaluated post-12-month intervention with over 1000 individuals at the start of the study, a nine-month analysis of 1,095 individuals, and a 12-month examination of 945 individuals. Results of the study at nine months revealed 13-pound WL when exercise increased from 66 minutes to 116 minutes. The 12-month results showed a 10-pound WL; however, exercise decreased from 116 minutes to 91 minutes. Both studies suggest that telehealth plays a role in weight and exercise improvements.

Descriptive Results

This IR aimed to analyze articles focusing on telehealth, prediabetes, and T2DM to improve education to prevent the incidence of T2DM within the community. The IR examined 29 peer-reviewed articles to include various criteria to address the clinical question; Does the literature support telehealth education to improve the lifestyles of adults with prediabetes? It was imperative to review articles on diabetes education, NDPP, DSMES, prediabetes, lifestyle behaviors, readiness, nutrition, exercise, and mobile applications to accurately provide insight into the clinical question. However, the articles reviewed also included those components in addition to telehealth. The time frame of the literature review was between 2018 and 2023; excluded were articles for 2023 that did not have research results published. Appendices A-C provided a detailed presentation of the literature search categories and their Level of Evidence Hierarchy (Melnik & Fineout-Overholt, 2018).

The knowledge gained within the literature strengthens the perspective that telehealth is a platform to enhance an individual's proficiency with lifestyle modifications to reduce T2DM. The information obtained from the literature implies a strong correlation between education and

TELEHEALTH AND PREDIABETES

positive lifestyle behaviors (Somerville et al., 2019). To decrease the incidence of T2DM, individuals can make lifestyle changes with the reversible prediabetes diagnosis. Given this instance, the literature obtained in the IR related to T2DM, education, and telehealth applies to individuals with prediabetes.

Synthesis

The IR presented within the 29 articles provides an increased knowledge of telehealth education to improve lifestyle behaviors to prevent T2DM from occurring (Ahn et al., 2023, Alaslawi et al., 2022, AshaRani et al., 2021; Batten et al., 2022). The data gathered provided the information required to answer the clinical question (Toronto & Remington, 2020). Appendix C correlates the topic and author as a visual presentation. However, some articles utilized in the IR did not have results completed, but showed the importance of the issue at hand (Kasturiratne et al., 2021, Sarfati et al., 2018, Shakya et al., 2021).

Ethical Considerations

The project consisted of an IR in which the researcher had no contact with human subjects. In addition, no patient data were identified within the literature. Providing the information that ethical concerns did not apply to this IR, the Liberty University IRB approved the research (See Appendix E).

Timeline

A vital component of an IR is establishing a timeline to ensure accuracy and that all individuals reviewing the project are aware of the process. The timeline associated with the IR is annotated in Appendix D.

SECTION SIX: DISCUSSION**Implications for Practice**

The prevalence of prediabetes is rising; lifestyle modifications must be implemented to prevent T2DM from occurring in individuals with prediabetes. However, in the fast-paced, technology-driven world, it is crucial to utilize this platform to engage people with prediabetes (Alshehri & Alshaikh, 2021; Batten et al., 2022, Cannon et al., 2022; Kasturiratne et al., 2021; Kirley & Sachdev, 2018, Salmon et al., 2021, Sevilla-Gonzalez et al., 2022, and Signal et al., 2020). This IR aimed to establish a foundational framework to provide healthcare professionals with the resources necessary to develop and implement a telehealth educational program for individuals with prediabetes that will improve lifestyle behaviors. Implementing these lifestyle behaviors will decrease HbA1c, weight, or BMI, and increase physical activity, thus reducing the risk of T2DM. In addition, providing education through telehealth gives the underserved access to valuable information and resources to prevent T2DM. In addition, those with limited transportation or who cannot travel and the underserved can access educational material through telehealth platforms (Aberer et al., 2021).

The study also provides an excellent foundation for telehealth and how to implement programs. Synthesizing the literature and allocating it into the different compartments specific to answering the clinical question increased the effectiveness of the IR.

Limitations of the IR consist of the literature on prediabetes compared to T2DM and telehealth with lifestyle modifications. Although a limitation to the study, knowledge obtained and implemented for T2DM can be utilized for prediabetes. Another limitation of the study is the

TELEHEALTH AND PREDIABETES

English language search strategy. Besides language limitations, the search for prediabetes and telehealth could have missed relevant literature.

The study's primary strength includes the wide variety of literature that determined telehealth was a positive intervention in diabetes management. The focus of the literature review was broad and included telehealth, prediabetes, lifestyle modifications, T2DM prevention, and T2DM education. All the knowledge combined reveals how a telehealth education program can improve the lifestyle behaviors of adults with prediabetes. A secondary strength of the IR included annotating behavioral processes and the knowledge of the healthcare professionals as a critical component before any favorable lifestyle modification can occur.

Dissemination

The literature review provided an in-depth analysis to develop new perspectives on the need to utilize telehealth to educate individuals with prediabetes (Cannon et al., 2022). The literature synthesis also increases the foundational knowledge for healthcare professionals on the importance of positive lifestyle behaviors, eating healthy, and exercising to improve overall health outcomes. However, understanding the limitations and barriers associated with technology, it is still crucial to understand the benefits of motivating healthcare professionals to utilize this platform to change the lifestyle behaviors of individuals with prediabetes. This IR will be submitted to Scholars Crossing for publication to increase healthcare professionals' knowledge of telehealth and its position with individuals with prediabetes. A follow-up to the IR would be conducting an evidence-based research project within the community to enhance the literature on prediabetes and telehealth.

Re: IRB Application - IRB-FY22-23-1306 Does A Telehealth Education Program

Improve Lifestyle Behaviors of Individuals with Prediabetes? An Integrative Review

Dear Loretta Richardson and Debra Maddox,

The Liberty University Institutional Review Board (IRB) has reviewed your application in accordance with the Office for Human Research Protections (OHRP) and Food and Drug Administration (FDA) regulations and finds that your study does not meet the definition of human subjects research. This means you may begin your project with the data safeguarding methods mentioned in your IRB application.

Decision: No Human Subjects Research

Explanation: Your study is not considered human subjects research because it will not involve the collection of identifiable, private information from or about living individuals (45 CFR 46.102).

Please note that this decision only applies to your current application. Any modifications to your protocol must be reported to the Liberty University IRB for verification of continued non-human subjects research status. You may report these changes by completing a modification submission through your Cayuse IRB account.

If you have any questions about this determination or need assistance in determining whether possible modifications to your protocol would change your application's status, please email us at irb@liberty.edu.

Sincerely,

G. Michele Baker, MA, CIP

Administrative Chair of Institutional Research

Research Ethics Office
